## Abstract

Abstract is the last thing to write - keep that with line at the beginning of the code

## Author summary

I don't publish in plos One so I'm not sure why this is here.  
*Text based on plos sample manuscript, see*

## Introduction

Collecting and synthesizing data that is aligned with fishery management goals is essential for the long term sustainability of fishery resources. Data used to manage fisheries are derived from two principle sources: fishery-dependent data (scientific surveys) and fishery-independent data (collected from active participants in the fishery). The collection of fishery-independent data is preferred as it is less prone to bias and confounding effects that can arise from individual fisher behavior including skill and gear selection. Although preferred, fishery-independent data are expensive to collect leaving fishery-dependent data as an attractive alternative. Depending on the value of the fishery, the use of fishery-dependent data can have dire consequences. Indeed, one of the causes of the worlds greatest fishery collapse (Atlantic cod) was a result of weighing commercial fishery catch-and-effort data in the analyses of population trends (see my thesis for reference for this). There are however, ways to include fishery independent data and it plays a large role in the management of commercial fisheries (Tuna - see Maunder GLM paper). This is possible for large scale fisheries where catches of individual vessels can be accounted for in the analysis but this is less practical for relatively small scale recreational fisheries.

New technologies are allowing for the easy and remote collection of recreational fishing data. These data are collected by mobile apps where fishers opportunistically enter their catches and include other informataion such as size, species and even location. These apps collect individual fishing behaviour so that can be controlled in the analysis but still suffer from gear and effort issues.

Ways to control for this

- Structure surveys via derbies 26
- Model individual fisher behaviour (maybe we could use age for experience?) 27
- Use derbies as a way to build catchability effectiveness of gear types? 28

How this paper should proceed 29

- Simulation? 30
- make a table of warts of recreational fishery data 31
- 32

Here are two sample references: [1,2]. 33

#Bridge between fishery dependent and fishery independent data 34

## Structure of the paper 35

### Recreational fishing derbies Angling data alone 36

- truncated measure of size structure 37
- relative abundance 38
- Table of common fishery metrics - fishery independent - fishery independent 39

limitations of fish independent - expensive, high effort 40

limitations of fishery dependent - more effort 41

Fixed gear - choice of single or multiple lures 42

increased power using both methods 43

### #Confounding factors 44

### Mark recapture monitoring 45

### Equations 46

Here is an equation: 47

$$f_X(x) = \left(\frac{\alpha}{\beta}\right) \left(\frac{x}{\beta}\right)^{\alpha-1} e^{-\left(\frac{x}{\beta}\right)^{\alpha}}; \alpha, \beta, x > 0.$$

Here is another:

$$a^2 + b^2 = c^2. \tag{1}$$

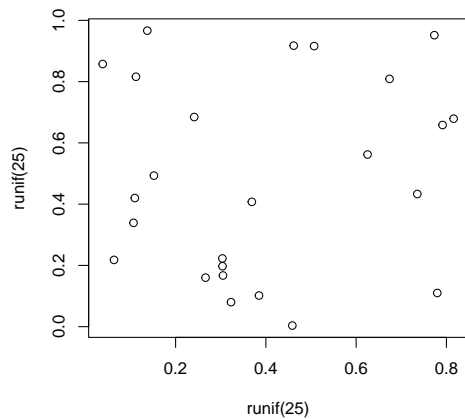

Inline equations:  $\sum_{i=2}^{\infty} \{\alpha_i^{\beta}\}$  48

### Figures and tables 49

Figure 1 is generated using an R chunk. 50

### Tables coming from R 51

Tables can also be generated using R chunks, as shown in Table 1 for example. 52

**Fig 1.** A meaningless scatterplot.

```
knitr::kable(head(mtcars)[,1:4],
  caption = "\\label{tab1}Caption centered above table"
)
```

**Table 1.** Caption centered above table
